

Householder XI Continues the Gatlinburg Tradition

By John de Pillis

During the week of June 18, 1990, the Eleventh Householder Symposium on Numerical Algebra took place at the Nya Hotel Tylosand, on the west coast of Sweden, near the town of Halmstad. The approximately 150 attendees were a truly international group, with a large contingent from the Soviet Union and Eastern Europe—a first for these meetings.

Some participants arrived on Sunday, June 17, to register and settle in early. Friends old and new made contact, and various groups set out in search of local restaurants to share some time and their first meal in Halmstad. Recovery time was required for some victims of price-shock.

In certain respects, the casual visitor might conclude that the charming Nya Tylosand is not so much a hotel as an intelligence test. This impression was due, in part, to the numbering system of the rooms (for which no algorithm seems to exist) and to the helpful signs "HISS" and "RUM" ("elevators" and "room.")

Formal Talks

There were so many interesting lectures (often in conflict) that it would be impossible to give more than a fleeting impression of the meeting in this space. The rich and stimulating sessions showed the growing use of numerical linear algebra in an ever-widening range of

applications. The many young persons in attendance provided further evidence of a stronger interest in the field than ever before.

The conference opened on Monday, June 18, with welcoming remarks from organizing committee chair Åke Björck. Gene Golub, extending Björck's greetings, mentioned that of the original organizers of the Householder (formerly called Gatlinburg) conferences, only David Young and Golub himself had attended every meeting. Velvel Kahan had also attended the very first meeting, held in Gatlinburg in 1961.

In the opening talk, James Demmel described some of his work on LAPACK, a sparse matrix library being designed for accuracy and portability, qualities that are not easy to realize on Cray computers! (See the "Informal Talks" section for a Cray test you can do at home.) Using component-wise relative error (as opposed to the more standard relative norm bounds), Demmel was able to achieve tighter error bounds in, for example, the solution of linear systems, generalized singular value decomposition, and the symmetric eigenvalue problem. The morning continued with Kahan's talk on symmetric rank-1 perturbed diagonal systems, along with some observations on the arithmetic weaknesses of the Crays.

K. Veselic gave more details on the accuracy of the one-sided Jacobi method as applied to $L'L = A$, in comparison with the use of the QR algorithm. The error bounds were element-wise, as described by Demmel, and were convincing enough to make Jacobi the method of choice for the LAPACK project.

Nicholas Higham talked about fast matrix multiplication, describing recent developments based on Strassen's algorithm (look for Higham's discussion of the practical use of fast matrix multipliers in an upcoming issue of *SIAM News*). The "usual" matrix multiplication involves an n^2 error term. In Strassen's method, the error exponent p for n^p ranges from 2 to 3.85, and the numerical error can be 10 to 100 times greater than that for standard multiplication.

Both IBM and Cray use Strassen's method in their libraries. Roger Grimes pointed out that Strassen's method requires more memory and

so cannot be implemented in the level 3 BLAS (Basic Linear Algebra Subprograms) as a default. Kahan noted that the BLAS3 perform well with scaling but that Strassen's method does not.

Mario Arioli gave examples in which the use of a QR factorization to solve nonsingular systems resulted in errors much larger (up to 15 orders of magnitude) than did LU. His explanation was an error analysis that accounts for the

sparsity pattern of each Q_i (again, c.f. Demmel's talk). Normally, QR perturbs the entire upper triangle of A , not just the nonzero parts. Arioli also showed that QR cannot capture Skeel's error bounds for LU, but that it does yield the classical condition number.

Christian Bischof and Robert Plemmons both gave talks about condition estimators. Bischof discussed the application of his incremental condition estimator (ICE) in the context of sparse orthogonal factorization. Plemmons surveyed the work he has done with Dan Pierce, Gene Golub, and William Ferng on adaptive condition estimators (ACE and ALE) and their application to recursive least squares computations in signal processing.

New approaches for the iterative solution of nonsymmetric systems were the focus of three interesting plenary talks. In the first, Roland Freund suggested that use of his quasiminimal residuals (QMR) algorithm can be extended beyond the complex symmetric case. Unfortu-

nately, it seems that QMR can fail in the same cases in which incurable breakdowns occur in the Lanczos algorithm.

Henk Van der Vorst then presented the stabilized conjugate gradient scheme (CGS) and suggested that it might be combined with QMR. The basic idea is that in biconjugate gradients, a polynomial P_i is created such that $P_i(A)$ reduces r_0 to r_i , and $P_i(A^T)$ reduces r'_0 to r'_i . CGS uses $(r_i, r'_i) = (P_i(A)P_i(A^T)r_0, r'_0)$ to get a recursion for r_i with no need for r'_i . The polynomial P_i is effectively squared, however, so that any conditioning problems with P_i are exacerbated. Van der Vorst also noted that $P_i(A)r_0$ is orthogonal to $Q_{i-1}A^T r'_0$ for any polynomial Q of degree less than i . He recommends using $Q_i(A) = (I - \alpha_i A)(I - \alpha_{i-1} A) \dots (I - \alpha_1 A)$, with the parameters α_i chosen to minimize the norm of r_i . The resulting CGSTAB algorithm has a smooth convergence of residual norms and better performance than GMRES(k) or CGS; it has never broken down on device simulation problems.

Finally, Lothar Reichel presented a hybrid method that combines Richardson's method and GMRES(k). Reichel proposed that GMRES(k) be used to find the parameters for a Richardson iteration, with Leja points used to order the parameters. His approach for finding the parameters seems to differ from that used by Saylor, Smolarski (the pronunciation of which is left to the reader's discretion), Saad, and Elman—instead of using the underlying Arnoldi iteration, he uses the GMRES residual polynomial directly. He suggests that the new method has better properties because the GMRES residual polynomial captures the ϵ -pseudospectrum (defined by Trefethen), while the Arnoldi approach does not.

Olof Widlund showed results from SESAM, a large finite element code for elasticity problems. He proposed eliminating interior nodes, that is, explicitly forming the Schur complement. He then tested three block preconditioners, based on the use of a coarse grid, the edge space of leftover unknowns, and the vertex space of leftover unknowns. The last choice provided the best preconditioner by far.

Kahan asked about nonlinear problems, where

Put idle cycles to work with

The Network Linda System[®] for Homogeneous LANs

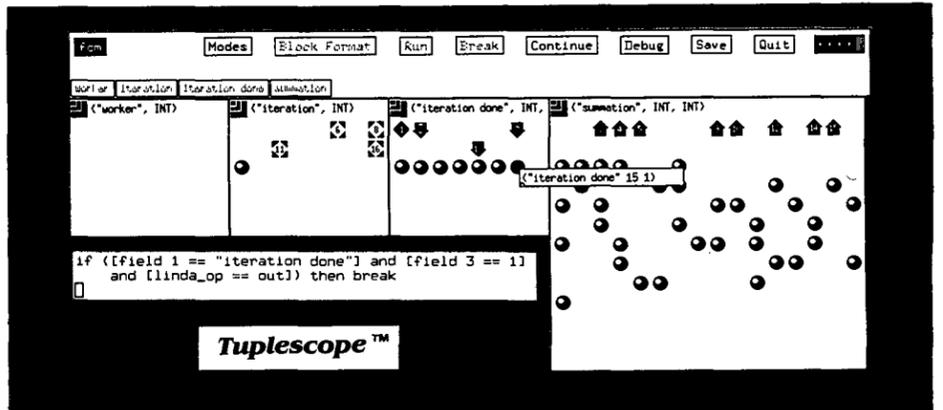

The C-Linda environment provides a simple, portable, and efficient framework for parallel programming. Now Linda provides convenient access to parallelism on homogeneous computer networks. The Network Linda System lets you form a virtual supercomputer from unused CPU cycles in an existing network. Programs written in C for the shared-memory or distributed-memory Linda systems can run also, without modification, on The Network Linda System.

- "Buy" a supercomputer without paying a cent for more hardware
- Develop Linda[®] code that can be run on LANs or multiprocessors

The Network Linda System is designed to run on Unix 4.3BSD machines, linked through a network. It uses the TCP/IP network protocols supported by the 4.3BSD interprocess communications mechanism (IPC). The Network Linda System for Sun 3 and Sun Sparcstations currently is available. Ports to other platforms are in process.

The basic system is designed for nodes on a homogeneous network...

- A compiler to take Linda input, perform analysis and optimizations, and produced parallel code to run on the network. The Network Linda System uses the same precompiler and analysis modules as SCIENTIFIC's other commercial Linda systems.
- Code development system to write, debug, and execute Linda codes on each workstation. This system includes a graphical debugging tool (a "Tuplescope"—sample shown at right). Also includes a runtime support library.

To order The Network Linda System or get more information, write, FAX or e-mail linda@sca.com

246 Church Street, Suite 307, New Haven, CT 06510.
Call SCIENTIFIC at (203) 777-7442...or FAX (203) 776-4074.

Householder XI,*continued from page 24*

structural failure usually begins in the local elements (which are eliminated by Widlund's scheme) and then work their way up to larger structures. Widlund had no answer, having tested only linear problems. Roger Grimes mentioned that this approach is too expensive for three-dimensional problems, since what is left over consists of planes, not lines. Tony Chan bounced around in his chair at this comment but did not have a chance to respond until the next break. I did not hear his response, but apparently he considers the approach practical even for three-dimensional problems and has written something to that effect.

A. Yu Yeremin also proposed explicitly forming the Schur complement for elasticity problems, in spite of the additional storage and the large number of operations required. He suggested using an incomplete BSSOR-CG scheme as preconditioner-solver pair, unlike his previous work, in which he used a complete BSSOR preconditioner. The incomplete BSSOR is based on the use of an incomplete Cholesky factorization of the diagonal blocks of the matrix, rather than the complete factorization.

In the following talk, L. Yu Kolotilina discussed the use of direct approximations to the inverse of the matrix as preconditioners and presented a method for obtaining a symmetric approximation when A is symmetric and positive definite. When applied to elasticity problems, the preconditioned system has a larger condition number than the unpreconditioned system! However, significant improvement over BSSOR-CG and IBSSOR-CG is achieved when the Schur complement is used instead.

Only a few of the many other excellent talks given at the conference can be mentioned here. Certainly worth mentioning was Angelika Bunse-Gertner's talk on computing the eigendecomposition of unitary matrices; Bunse-Gertner showed that application of the QR algorithm to the Schur parameter form of a unitary matrix, and not to the unitary matrix itself, makes it possible to take advantage of many of the zeros that occur for free during the bulge-chasing sequence.

Sabine Van Huffel gave an excellent overview and introduction to total least squares, providing motivation, basic analysis, and guidelines as to when total least squares should and should not be used (the alternative is regular least squares). Per-Åke Wedin, in an overview of perturbational analysis of linear and nonlinear least squares problems, advocated the use of iterative refinement for such problems. His analysis showed essentially that the dependence on the square of the condition number can be removed by this approach.

As always, much of the action at the Householder Conference took place in special sessions. One especially notable special session dealt with row projection methods. A. Dax of the Hydrological Service in Israel discussed the application of Kaczmarz methods for solving l_∞ , l_1 , and linear programming problems by a regularization approach. M. Neumann refined his analysis of the convergence of chaotic iterations, and Mario Arioli presented further results for the application of Cimmino's method to sparse nonsingular systems.

The Householder Prize

The Householder Prize, given in recognition of outstanding PhD dissertations in numerical analysis/algebra, was awarded jointly to Alan Edelman (PhD, MIT; adviser, Nicholas Trefethen) and Maria Beth Ong (PhD, University of Washington; adviser, Loyce Adams).

At the Thursday night banquet, Pete Stewart formally thanked the names of the winners, noting the exceptionally high quality of the submissions, which had rendered the committee's choice pleasantly difficult. On Friday, Edelman presented his results on eigenvalues and condition numbers of random matrices. It was generally agreed that his results were beautiful and that his presentation was delivered with clarity and style.

Sad to say, Ong had some sort of visa problem with the U.S. Immigration Service and was

not able to make the trip to Sweden to present her results. It was rumored that INS thought her Green's function should also have a green card (what else?), but in all fairness, this report is totally unsubstantiated.

The audience was invited to confirm an odd anomaly—the Cray computations of both (62.0 x 63.0)/62.0 and (63.0 x 63.0)/63.0 return values that are not integers.

Informal Talks

Evening sessions, spontaneously organized to supplement the formally scheduled daytime talks, were very well attended. One of the informal talks, given by Velvel Kahan immediately after the Thursday banquet, actually served as the postbanquet entertainment. His lively and provocative discourse provided more detail about Cray arithmetic. The audience was invited to confirm an odd anomaly—the Cray computations of both (62.0 x 63.0)/62.0 and (63.0 x 63.0)/63.0 return values that are not integers.

Hans Schneider made some remarks in support of ILAS, the International Linear Algebra Society. Speaking to professionals whose very business it is to understand the notions of "less than" and "greater than," Schneider noted that the annual dues for this organization amounted to less than the cost of two Swedish beers.

For anyone interested (and there were many), Cleve Moler demonstrated a preliminary version of a proposed addition to Matlab for the handling and graphing of sparse matrices.

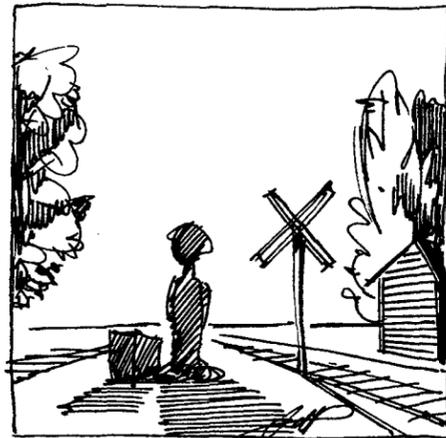

Local Color

Wednesday afternoon was set aside for an excursion to a wildlife refuge on an island off the coast. Many cheerfully piled into the Skandia buses for the trip to the harbor, where a roofless ferry awaited us. Only after we reached the island did the rains begin. Just a drizzle, nothing that could result in any diminution of The Experience. However, those of us who failed to bring umbrellas or raincoats were left in a state of soggy contrition after our return trip on the roofless ferry. At least the bus was covered.

The last day of the conference was June 22, the longest day of the year. Midsummer's Day, as it is known in Sweden, is marked with folk-dancing around special poles. But given the ghost-town emptiness of the streets, it is apparently mainly a time to stay at home and celebrate. For me, a Midsummer's Day departure from Halmstad meant a train station that had no passengers, no station master, and it appeared for a while, no train. But the train finally did appear, like a soundless Flying Dutchman with only one or two passengers (strangers, like me, to the Swedish ways).

Householder XI was a remarkably good meeting—the organizers are to be congratulated, and special thanks are due to Åke Björck for all his attention and consideration!

Several participants went on to other conferences on leaving Halmstad. Golub, along with Nancy Nichols, Paul van Dooren, and several others, stayed in Sweden to attend the meeting of SIAM's Nordic Section in Stockholm immediately following Householder XI. Demmel, Plemmons, and Young were off to Moscow, where they were to lecture at the USSR Academy of Sciences.

John de Pillis, a professor of mathematics and computer science at the University of California at Riverside, wrote and illustrated this article. He thanks Randy Bramley and Bob Plemmons for the use of their notes and Gene Golub for his observations.

Gene Golub and Tony Chan are the organizers of the next Householder Conference, Householder XII, which will be held at the University of California's Lake Arrowhead Conference Center in southern California in June 1993. Watch the SIAM News Calendar for further details.

INTEGRALS AND SERIES, VOLUME 3, MORE SPECIAL FUNCTIONS

A.P. Prudnikov, Head of the Department of Mathematical Physics of the Computing Center of the USSR Academy of Sciences, Moscow

Yu.A. Brychkov, Senior Research Associate of the Computing Center of the USSR Academy of Sciences, Moscow

O.I. Marichev, Associate Professor of the Byelorussian State University, Minsk, USSR translated from the Russian by G.G. Gould

"Truly extraordinary - and for applied mathematicians invaluable." - SciTech Book News

Continuing the "impressive tabulation of definite and indefinite integrals, as well as partial and total summations of series" (Choice), the third volume in this remarkable series provides a wealth of information on more functions—Struve, Weber, Anger, Laguerre, Bateman and Legendre—to name a few. Logically organized for easy and effective use, the handbook also contains unique material on properties and extensive tables of generalized hypergeometric functions, and of Mellin transforms of elementary and special functions combined with tables of special cases of the Meijer G-function. Providing mathematicians, physicists and engineers with the most comprehensive tables of integrals currently available, the results in this book allow the reader to calculate many further integrals and series.

Hardcover / Pages: 820 + ii / ISBN: 2-88124-682-6
1989 / \$175.00 (list) / \$50.00 (price for individuals)*

**INTEGRALS AND SERIES, VOLUME 1, ELEMENTARY FUNCTIONS
INTEGRALS AND SERIES, VOLUME 2, SPECIAL FUNCTIONS**

A.P. Prudnikov, Yu.A. Brychkov, and O.I. Marichev, USSR Academy of Sciences, Moscow

"Certainly one of the most important reference books for mathematicians, physicists, engineers, and others working in fields where such formulas are likely to occur."
- Mathematics of Computation

"An impressive collection of formulas...Each chapter is quite detailed and, with the aid of the table of contents, location of material is rather easy...a valuable addition to an applied worker's bookshelf."—American Mathematical Society

COMPLEX VARIABLES

Theory and Application, An International Journal

Editors: Robert P. Gilbert, University of Delaware

Klaus Habetha, Aachen University of Technology

Devoted to function theory, generalizations of these ideas, and their applications. Topics covered are schlicht functions, quasiconformal mappings, Hardy spaces, complex approximation theory, capacity functions, modular forms, Riemann surfaces, as well as hyperanalytic function theory, first-order elliptic systems, singularity theory, holomorphy domains, subharmonic functions, and other topics of classical, general variable theory. The applications, of course, may come from all branches of the sciences and engineering, but should be predominantly concerned with the novel use of complex analysis to solve a particular problem.

4 issues per volume—ISSN: 0278-1077
Current Subscription: Volumes 14-15 (1990)
Base List Price per volume: \$176.00*

LINEAR AND MULTILINEAR ALGEBRA

Editors: Marvin Marcus and Robert Thompson, University of California, Santa Barbara

Publishes research papers, research problems, expository or survey articles at the research level, and reviews of selected research level books or software, in linear and multilinear algebras and cognate areas. Appropriate areas include spaces over fields or rings, tensor algebras or subalgebras, non-negative matrices, inequalities in linear algebra, combinatorial linear algebra, matrix numerical analysis, plus other areas including representation theory. Lie theory, invariant theory, and functional analysis.

4 issues per volume—ISSN: 0308-1087
Current Subscription: Volumes 27-28 (1990)
Base List Price per volume: \$220.00*

JOURNAL OF STATISTICAL COMPUTATION AND SIMULATION

Editor: Richard G. Krutchkoff, Virginia Polytechnic Institute and State University

Publishes significant and original work in areas of statistics which are related or dependent upon the computer. Fields covered include computer algorithms related to probability or statistics, studies in statistical inference by means of simulation techniques, and implementation of interactive statistical systems.

4 issues per volume—ISSN: 0094-9655
Current Subscription: Volumes 34-35 (1990)
Base List Price per volume: \$202.00*
